# The Mancoosi Project

The mancoosi project (now concluded) focused among other things on the development of QA tool for FOSS distributions. More specifically we developed a suite of tools to:

- detect packages that are not installable or that cannot be compiled.
- detect packages that are outdated in the archive.
- identify classes of “important” packages.
- identify packages the if migrated to a specific future will break a large number of other packages.

  - 4 Upcoming
    - Coinst

- 2005 First version of edos-debcheck (written by J. Vouillon)
- 2006 Integration of edos-debcheck in dose 2
- 2006 Edos-Debcheck uploaded to debian, mandriva, caixa magica ...
- 2009 Complete re-write as part of dose 3 (Distcheck)

# Features

- Use special purpose sat solver
- Accept in input different formats (deb, rpm, eclipse)
- Handle compressed archives
- Use CUDF as internal generic format
- YAML output for simple parsing / integration
- twice as fast compared to edos-debcheck (with more room for improvement)

A demo is better than a 1000 words

# Where is it used

- EmDebian
- Mandriva QA team
- Caixa Magica QA team
- Debian Weather
- simple-cdd
- file-conflicts
- ...

- 
- 1 Mancoosi and FOSS
  - 2 Problems' Detection
    - Distcheck
    - Deb-Buildcheck
    - Outdated packages
  - 3 Problems' Avoidance
    - Strong dependencies
    - Challenged Packages
  - 4 Upcoming
    - Coinst

- Deb-specific for the moment (rpm version upcoming)
- Faster than edos-buildcheck (native application now)
- Same output format of distcheck
- It works by encoding the build dependencies and check if they can be satisfied w.r.t. a set of binary packages

# Output example

```
package: src:tulip
version: 3.1.2-2.3
architecture: any
source: tulip (= 3.1.2-2.3)
status: broken
reasons:
-
conflict:

    - Outdated packages
  - 3 Problems' Avoidance
    - Strong dependencies
    - Challenged Packages
  - 4 Upcoming
    - Coinst

# Why packages are broken (not installable) ?

- Transient problems
  - Depend on a package that is not available
  - Depend on a package that is not installable

# Why packages are broken (not installable) ?

- Transient problems
  - Depend on a package that is not available
  - Depend on a package that is not installable
- Non Transient problems : **Package needs update - there is a problem in the metadata of a package.**

# Trivial Example 1: Is (*foo*,1) installable?

```
Package: foo  
Version: 1  
Depends: bar ( = 2 )
```

```
Package: bar  
Version: 1
```

Is it installable in a future?

Yes, we just need to upgrade bar to version 2.

## Trivial Example 2: Is (*foo*,1) installable?

```
Package: foo  
Version: 1  
Depends: bar ( < 2 )
```

```
Package: bar  
Version: 2
```

Is it installable in a future?

No, because the dependency bar with version lesser then 2 and it will never be satisfied.

## Example 1: Is $(foo,1)$ installable?

```
Package: foo  
Version: 1  
Depends: baz (= 2.5) | bar (= 2.3),  
            bar (> 2.6) | baz (< 2.3)
```

```
Package: bar  
Version: 2
```

```
Package: baz  
Version: 2  
Conflicts: bar (< 3)
```

Is it installable in a future?

Yes, for example in a future with  $(baz,2.5)$  with no conflicts and  $bar$  with a version between 2.6 and 3.

## Example 2: Will (*foo*,1) ever be installable?

```
Package: foo  
Version: 1  
Depends: baz (= 2.5) | bar (= 2.3),  
bar (> 2.6) | baz (< 2.3)
```

```
Package: bar  
Version: 2.3
```

```
Package: baz  
Version: 2.5  
Conflicts: bar (> 2.6)
```

Is it installable in a future?

In this case this is not longer true, as if I choose baz (= 2.5) this will conflict with any version of bar greater then 2.6 and I cannot choose bar (= 2.3) because because baz is in the repository with version = 2.5

A demo of an automatic tool is fun !

# Problem with normal dependencies

The explicit, syntactic dependency relation  $p \rightarrow q$  is too coarse grained to answer natural questions like:

- *can I remove package  $p$  without affecting package  $q$ ?*
- *how many / which packages will be affected by the upgrade of package  $p$ ?*
  - **Impact set:** the set of packages potentially affected by changes in a given package.
  - Its size is the **package sensitivity**.
  - Direct dependencies: too little
  - Transitive closure of direct dependencies: too much

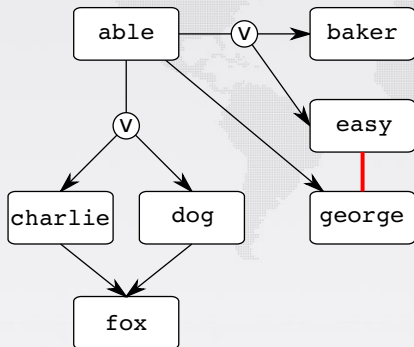

Answers do not depend on packages  $p$  and  $q$  only!

We need a stronger notion.

# Strong dependencies

## Definition

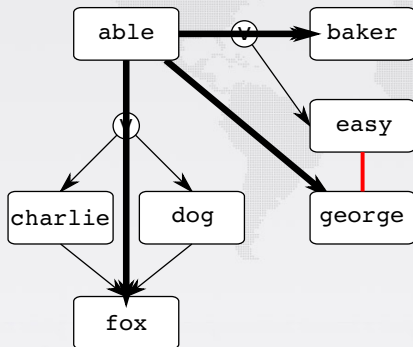

- $p$  strongly depends on  $q$  with respect to  $R$  if it is not possible to install  $p$  without also installing  $q$

# Strong dependencies

## Definition

- $p$  strongly depends on  $q$  with respect to  $R$  if it is not possible to install  $p$  without also installing  $q$

- george: conjunctive dependency
- baker: disjunctive, but easy not installable
- fox: dependency of both alternatives

# Impact sets via *Strong* dependencies in Debian

**Table:** Debian Lenny, sorted by the size of the strong impact set.

Package	—IS(p)—
gcc-4.3-base	20128
libgcc1	20126

# Challenged Packages

- By looking at the impact set of a package  $P$  We can deduce which packages are affected by a problem in  $P$ .
- We want to know something more : if I upgrade a package  $P$  with version  $v$  to a future version  $w$ , how many packages are going to be affected by this upgrade ?
- We want to do this only by looking at the current repository and only using the available meta data information.
- We also consider clustering information to upgrade all packages in a cluster at once

Nope, this one takes some time to run...

# Results for Squeeze

**Table:** Top 20 cluster upgrades, by number of broken components
